Dedicated To
My Affectionate Parents,
Brothers And Sisters.
Special Dedication To
My Father ,AliAbdAl-Ghani
My Mother Amenah
My Wife ,Falasteen
My Son ,Yaman, and
My daughter Aleen.
With my Respect and Love.

## Acknowledgments:

I would like to express my deep appreciation and respect to Prof. Ismail warad( Advisor ) for his direct supervision, encouragement and help throughout the course of this work. Also, I would like to thank my committee members, Prof. Mohammed Al-Nuri, Dr.Nizam Diab and Dr. Ashraf Swafta for their fruitful discussions.Special thanks are due to my father, Ali, my mother, Amenah, and my wife, Falasteen, for their support and encouragement. Special thanks are extended to my brothers Nofal andMohammad,And to my sisters, Bothaina, Arwa ,Maisaa,Tasneem, and Sojoud,and to my kids Yaman , Aleen and wisam.Thanks are also extended to my friends and to Mr. Nafith Dwikat for his helping and support during my work in the laboratory.

Synthesis, Spectral, Thermal, Electrochemical Characterization of New Family of Semi-Octahedral Diamine / Copper (II) Complexes and their Biological Activities<br>By<br>BahaaAbd Al-Ghani<br>\section*{Supervisor}<br>Prof. Ismail Warad

#### Abstract

Our research focuses on synthesis of novel compounds which are expected to be excellent donating compounds in coordination chemistry besides synthesis of their complexes.

Four new hydrated monocationCu(II) complexes with 1,3propylenediamine and1,2-ethylenediamine with chloro or bromo ligands were prepared in acceptable yield. The complexes were spectrally characterized by (IR, UV-visible, and TOF-MS) as well as by thermal (TG/DTA) and elemental analysis. The three dimensional structure for complexes 2,4were proved by X-ray diffraction studies, which show the $\mathrm{Cu}(\mathrm{II})$ is coordinated by four nitrogen atoms of the base ligand and one bromide ion or chloride ion. In the crystal structure, molecules are connected through intermolecular dipole interactions of the type $\mathrm{N}---\mathrm{H} . . . \mathrm{Br}$ and hydrogen bond N---H...O. Additionally, an intramolecular hydrogen bond of the type $\mathrm{C}---\mathrm{H} . . . \mathrm{Br}$ is observed; these interactions lead to a three dimensional architectural packing in the crystal structure. Hirschfeld surfaces computational method was used to figure out the intercontacts in the crystal structure, the data showed that intercontacts of the type H...H (52.8 \%), H...Br (32.7 \%), H...O (12.4 \%) and Br...O (2.1 \%) were
observed and quantified. Antitumor activity of the desired complexes was evaluated. The results revealed high antitumor activity against several types of cancer cells.

## Chapter One

## Introduction

### 1.1 The aim

The aims of this study were:

* Four Cu (II) complexes were prepared: five coordinated monocationic-monohydrated-halo-Bis-propane-1,3diamine/Copper(II) halide complexes.
* The desired complexes were characterized by several available spectral analysis techniques like: IR, UV-Visible, TG/DTA, EA, MS, CV, EDX, and SEM.
* X-ray Single crystals diffraction was investigated to identify the structural formulas of crystalline complexes 2 and $\mathbf{4}$
* ComputationalHirschfeld surface analysis ofcomplexes 2 and 4 were carried out, in order to compare both theoretical and experimental spectral analysis.
* The complexes were evaluated as DNA-binder as well as antitumoractivities.

### 1.2. Organometallic Chemistry:

Organometallic compounds, with their metal-carbon bonds, are placed at the interface between classical organic and inorganic chemistry in dealing with the interaction between inorganic metal species and organic molecules [1-3]. The organometallic field has provided a series of important conceptual insights, surprising structures, and useful catalysts both for industrial processes and for organic synthesis. Many catalysts are capable of very high levels of asymmetric induction in preferentially forming one
enantiomer of a chiral product. The field is a beginning to make links with biochemistry with the discovery of enzymes that carry out organometallic catalysis [3-4]. Ideas drawn from organometallic chemistry have helped to interpret the chemistry of metal and metal oxide surfaces, both key actors in heterogeneous catalysis. The field is also creating links with the chemistry of materials because organometallic and metal-organic compounds are increasingly preferred as the precursors for depositing materials on various substrates via thermal decomposition of the metal compound. Nanoscience and nanotechnology are also benefiting with the use of such compounds as the most common precursors for nanoparticles. These small particles of a metal or alloy, with properties quite unlike the bulk material, are finding more and more useful applications in electronic, magnetic, or optical devices or in sensors [1-10].

Public concern for the environment has led to the rise of green chemistry, with the object of minimizing both energy use and chemical waste in industryand commerce. One strategy is atom economy in which reactions are chosen that minimize the formation of by-products or unreacted starting materials.

For example, rhodium or iridium-based catalysts directly convert MeOH and CO to MeCOOH with no significant by products. Organometallic catalysis is likely to be a key contributor when climate change becomes severe enough to force government action to mandate the use of renewable fuels [4-6]. The presence of $d$ electrons in their valence shell distinguishes the organometallic chemistry of the elements of groups 3-12 of the

Periodic Table, the transition elements, from that of groups $1-2$ and 12-18, the main-group elements. Group 12, and to some extent also group 3, often show greater resemblance to the main-group elements. Transition metal ions can bind ligands (L) to give a coordination compound, or complex MLn , as in the familiar aqua ions $[\mathrm{M}(\mathrm{OH} 2) 6]^{2+}(\mathrm{M}=\mathrm{V}, \mathrm{Cr}, \mathrm{Mn}, \mathrm{Fe}, \mathrm{Co}$, or $\mathrm{Ni})$. Organometallic chemistry is a subfield of coordination chemistry in which the complex contains an $\mathrm{M}-\mathrm{CorM}-\mathrm{H}$ bond. Organometallic species tend to be more covalent, and the metal is often more reduced, than in other coordination compounds. Typical ligands that usually bind to metals in their lower oxidation states are CO , alkenes, and arenes.. In this chapter we review some fundamental ideas of coordination chemistry, which also apply to organometallic complexes [1-15].

### 1.3 Stereochemistry:

The most common type of complex is $\mathrm{ML}_{6}$, which adopts an octahedral coordination geometry (1.1) based on one of the Pythagorean regular solids.

1.1

Octahedron

### 1.4 Chelate Effect

Other ligands can have more than one donor atom, each with its lone pair; an example is ethylenediamine $\left(\mathrm{H}_{2} \mathrm{~N}-\mathrm{CH}_{2} \mathrm{CH}_{2}-\mathrm{NH}_{2}\right)$, often abbreviated "en"). Such ligands most commonly donate both lone pairs to the same metal to give a ring compound, known as a chelate, from the Greek word for "claw" (1.2). Chelate ligands may be bidentate, such as ethylenediamine, or polydentate, such as $\mathbf{1 . 3}$ and $\mathbf{1 . 4}$

1.2

### 1.5 Why Copper?

Copper, a bio-essential element, plays an important role in biological processes that involve electron transfer reactions.Actually,copper(II)
complexes with $\mathrm{O}, \mathrm{N}, \mathrm{S}$ have been widely studied and they are proved to be good anticancer agents due to their strong binding affinity with DNA [2-14]. It has been demonstrated that copper assembles in tumors due to the selective permeability of cancer cell membranes to copper compounds [2-11]. It is a very impoal in life, photosynthesis process, mitochondrial respiratory, carbon and nitrogen rtant met metabolism, and oxidative stress protection [14].

### 1.6. Previous Work

The interaction and reactions of metal complexes with DNA have long been thesubject of intense investigation in relation to the development of new reagents for bio- technology and medicine. Among the metal complexes so far investigated, those of phenanthroline that have attracted much attention for their various functions. It is well known that copper(II) complexes of 1,10-phenanthroline (phen) inhibit DNA or RNA polymerase activities and induce strand scission of DNA in the presence of $\mathrm{OH}^{-}$or thiol [5-11]. The copper-phenanthroline complex cycles between $\mathrm{Cu}(\mathrm{II})$ and $\mathrm{Cu}(\mathrm{I})$ to catalyze the formation of activated oxygen species. In the course of such reactions, a tetrahedral $[\mathrm{Cu}(\mathrm{phen})]$ complex has been suggested to bind non-intercalatively in the minor groove of the DNA. The substituents on the phenanthroline ring influence the reactivity of the complexes with DNA [5-7]. For example, the copper(I) complex of 2,9-dimethyl-1,10phenanthro line, $[\mathrm{Cu}(2,9-\mathrm{dmp})]$, does not cleave DNA [5]. It has been also
reported that some ternary complexes of $[\mathrm{Cu}(\text { phen })]^{+2}$ have an antitumor activity [13].

Tris-phenanthroline metal complexes and their analogs have also attracted much attention for the chiral recognition of DNA double helices with the enantiomeric complexes and for the photochemical electron-transfer reactions initiated by the complex bound to DNA [3-13].In the case of $[\mathrm{Ru}(\text { phen })]^{+2}$, both an intercalative and non-intercalative binding modes have been proposed.

Although various binding structures have been proposedforthe phenanthroline complexes on DNA, the geometrical part that DNA-fiber electron paramagnetic resonance (EPR) ameters, that characterize the binding mode of the complexes, have scarcely been reported. We have shown that spectroscopy provides information on stereospecificity and dynamic principal axes of the $g$-tensors relative to the DNA-double properties of paramagnetic metal complexes bound to DNA [4,16-48]. One can estimate the angles of the helical axis from the changes in the EPR line shapes with the orientation of the DNA fibers in the magnetic field. The temperature dependent EPR line shapes give information on the motion of the complexes on DNA.

### 1.7 Novelty

1. Water soluble octahedral diaminecopper(II) complexes were prepared for the first time.
2. Novel 3D structure of such Copper-ligands coordinate were analyzed by XRD and compared by DFT optimized structures.
3. The antitumor activity of such complexes was developed depending on their structures.

## Chapter Two

## Experimental part

### 2.1 Chemicals

### 2.1.1 Solvents

## Table 2.1: Solvent'sName and Molecular Formula

### 2.2 Equipments

1. X-Ray Diffractometer (Mysore University, India) was used to determine the structure of crystalline compounds.
2. Perkin Elmer Spectrum 1000 FT-IR Spectrophotometer (An-Najah National University, Palestine) wasused to obtain the spectra of resulting ligands $L_{1}, L_{2}$ and their complexes 1-4.
3. TU-1901 Double-Beam UV-Visible Spectrophotometer (An-Najah National University, Palestine) was used to obtain the maximum wavelength for $\mathrm{L}_{1}$ and their complexes 1,2 .
4. NMR BrukerAvance II 400 Spectrometer at 298 K , with 5 mm PABBO BB-1H TUBES, using $\mathrm{CDCl}_{3}$ as a Solvent and TMS as Internal Standard (chemical shift in $\delta \mathrm{ppm}$ ) (Mysore University, India) was used to obtain NMR spectra of resulting ligands $\mathrm{L}_{1}, \mathrm{~L}_{2}$
5. TGA-7 PerkinElmer Thermogravimetric Analyzer (PerkinElmer Inc., Waltham, MA, USA) (Mysore University, India) was used to obtain TG/DTG for $L_{1}, L_{2}$, and their complexes 1,4 .
6. Thin-Layer Chromatography using Merck Silica Gel 60 F254 Coated Aluminum Plates (Mysore University, India) was used to determine the purity of the ligands $\mathrm{L}_{1}, \mathrm{~L}_{2}$.
7. EI-MS (Mysore University, India) was used to obtain the spectrum for $L_{1}$.

### 2.3 Synthesis

## Procedure to prepare the desired complexes

Complexes 1-4 were synthesized, in $80-90 \%$ yields. The corresponding hydrated $\mathrm{CuX}_{2}$ salt ( 1 mmol ) was dissolved in ethanol
$(10 \mathrm{~mL})$.To this solution, 2 mmol of propane-1,3-diamine or ethylenediamine dissolved in distilled water ( 1 mL ) were added. The reaction mixture was left for $\sim 10 \mathrm{~min}$ until appearance of deep blue color solution. Solvent was then evaporated under reduced pressure and the solid
residue was washed several times with alcohol and dichloromethane and then was left to dry.

## Complex 1

Yield 83\%, m.p. $=165{ }^{\circ} \mathrm{C} . \mathrm{MS}(\mathrm{m} / \mathrm{z}) 246.07 \quad[\mathrm{M}+]-\mathrm{Cl}$ for $\left[\mathrm{C}_{6} \mathrm{H}_{20} \mathrm{ClCuN}_{4}\right] \mathrm{Cl}$. ### 2.4 Instruments

A TU-1901 double-beam UV-visible spectrophotometer was employed to record the UV-visible spectra for complexes, whereas Infrared spectra (IR) were recorded on a Perkin Elmer Spectrum 1000 FT-IR Spectrophotometer. EI-MS data were obtained with the aid of a Finnigan 711A ( 8 kV ) (PerkinElmer Inc., Waltham, MA, USA) instrument. Thermogravimetric analysis (TGA) and differential thermal analysis (DTA) for both complexes were accomplished by using a TGA-7 Perkin Elmer thermogravimetric analyzer (Perkin Elmer Inc., Waltham, MA, USA). Elemental analysis ( $\mathrm{C}, \mathrm{H}$, and N ) for complex 2 was performed out with EuroVector EA3000 (C, H, and N) instrument, and the observed results agreed with the calculated percentages to within $\pm 0.4 \%$. We carried out Hirshfeld surface analysis for complex 2 using the program CRYSTAL EXPLORER 3.1 [34].

### 2.4.1 Single Crystal X-ray Diffraction

By a slow evaporation of ethanol from ethanolic solution of the complex, suitable crystal for X-ray diffraction measurements was collected. A blueprism single crystal of dimensions $0.27 \times 0.28 \times 0.26 \mathrm{~mm}$ of complex 2 was selected for X-ray diffraction measurements. X-ray intensity data were collected at a temperature of 293 K with the aid of a BrukerProteum 2 CCD diffractometer equipped with an X-ray generator operating at 45 kV and 10 mA , using $\mathrm{CuK}_{\alpha}$ radiation of wavelength $1.54178 \AA$. Data was collected for 24 frames per set with different settings of $\varphi\left(0^{\circ}\right.$ and $\left.90^{\circ}\right)$, keeping a scan
width of $0.5^{\circ}$, exposure time of 2 s , sample to detector distance of 45.10 mm and $2 \theta$ value at $64.5^{\circ}$. A complete data set was processed using SAINT PLUS [35]. Crystal structure was solved by direct methods and refined with full-matrix least squares method by means of the $F^{2} S H E L X S$ and $S H E L X L$ programs [36]. Geometrical calculations were carried out using the program PLATON [37], whereasthe molecular and packing diagrams were generated with the aid of the software MERCURY [38]. Details of the crystal structure and data refinement are given in Table 2.3.

## Table 2.3 Crystallographic data and structure refinement parameters

 for complex 2.| Empirical formula | $\mathbf{C}_{6} \mathbf{H}_{22} \mathbf{N}_{\mathbf{4}} \mathbf{B r}_{2} \mathbf{O C u}$ |
| :--- | :--- |
| Formula weight | 389.61 |
| Temperature | $293(2) \mathrm{K}$ |
| Wavelength | $1.54178 \AA$ |
| Crystal system, space group | Monoclinic, $P 2^{\circ} / c$ |
| Unit cell dimensions | $a=8.6858(5) \AA$ |
| Volume | $1326.95(13) \AA^{3}$ |
| Z, Calculated density | $4,1.940 \mathrm{Mg} / \mathrm{m}^{3}$ |
| Absorption coefficient | $9.230 \mathrm{~mm}^{-1}$ |
| $F_{(000)}$ | 764 |
| Crystal size | $0.26 \times 0.27 \mathrm{x} 0.28 \mathrm{~mm}$ |
| Theta range for data collection | $5.3^{\circ}$ to $64.5^{\circ}$ |
| Limiting indices | $-7 \leq \mathrm{h} \leq 10,-17 \leq \mathrm{k} \leq 15,-12 \leq 1 \leq$ |
| Reflections collected / unique | $5668 / 2107[\mathrm{R}($ int $)=0.039]$ |
| Refinement method | Full-matrix least-squares on $F^{2}$ |
| Data / restraints / parameters | $2021 / 0 / 128$ |
| Goodness-of-fit on $F^{2}$ | 1.11 |
| Largest diff. peak and hole | 1.22 And $-0.90 \mathrm{e} . \AA^{-3}$ |

Table 2.8: Crystal data and structure refinement for complex 4

| Empirical formula | $\mathrm{C}_{4} \mathrm{H}_{18} \mathrm{Br}_{2} \mathrm{CuN}_{4} \mathrm{O}$ |
| :---: | :---: |
| Formula weight | 361.58 |
| Temperature | 293(2) K |
| Wavelength | 0.71073 A |
| Crystal system | Monoclinic |
| Space group | P $121 / \mathrm{n} 1$ |
| Unit cell dimensions | $\begin{aligned} & \mathrm{a}=6.4422(4) \AA \alpha=90^{\circ} \\ & \mathrm{b}=15.4116(9) \AA \beta=98.048(6)^{\circ} \\ & \mathrm{c}=12.0398(9) \AA \gamma=90^{\circ} \end{aligned}$ |
| Volume | 1183.59(13) $\AA^{3}$ |
| Z | 4 |
| Density (calculated) | $2.029 \mathrm{Mg} / \mathrm{m}^{3}$ |
| Absorption coefficient | $8.567 \mathrm{~mm}^{-1}$ |
| F(000) | 708 |
| Crystal size | $0.3 \times 0.2 \times 0.2 \mathrm{~mm}^{3}$ |
| The range of data collection | 3.15 to $26.30^{\circ}$ |
| Index ranges | $-8<=\mathrm{h}<=7,-19<=\mathrm{k}<=17,-12<=\mathrm{l}<=15$ |
| Reflections collected | 5508 |
| Independent reflections | 2385 [R(int) $=0.0394$ ] |
| Completeness to theta $=26.30^{\circ}$ | 99.9\% |
| Absorption correction | Semi-empirical from equivalents |
| Max. and min. transmission | 1.00000 and 0.42392 |
| Refinement method | Full-matrix least-squares on $\mathrm{F}^{2}$ |
| Data / restraints / parameters | 2385 / 1/115 |
| Goodness-of-fit on $\mathrm{F}^{2}$ | 0.989 |
| Final R indices [I>2sigma(I)] | $\mathrm{R} 1=0.0422, \mathrm{wR} 2=0.0595$ |
| R indices (all data) | $\mathrm{R} 1=0.0675, \mathrm{wR} 2=0.0661$ |
| Largest diff. peak and hole | 0.683 and -0.649 e. $\AA^{-3}$ |

Table 2.9: Atomic coordinates ( $x \mathbf{1 0}^{4}$ ) and equivalent isotropic displacement parameters $\left(\AA^{2} \times 10^{3}\right)$ complex 4.

|  | $\mathbf{x}$ | $\mathbf{y}$ | $\mathbf{z}$ | $\mathbf{U}(\mathbf{e q})$ |

### 2.4.2 DNA binding

Experimental absorption titration spectra were carried out at pH 7.2 buffer solution of a Tris- $\mathrm{HCl}[5 \mathrm{mMTris}-\mathrm{HCl}, 50 \mathrm{mMNaCl}]$ and with a $\mathrm{Cu}(\mathrm{II})$ complex concentration of $5.0 \times 10^{-5} \mathrm{M}$. CT-DNA concentrations were varied between 0 and $1.0 \times 10^{-4} \mathrm{M}$ by keeping the total volume of mixture constant to 10.0 mL . The mixed solution of $\mathrm{Cu}(\mathrm{II})$ and CT-DNA was
allowed to equilibrate for 10 min at room temperature for each trial before being subjected to absorption measurements [48-53].

### 2.4.3 Biological assays

### 2.4.3.1 Preparation of stock solutions

A solution was made by dissolving 20 mg of each complex in 20 mL of Roswell Park Memorial Institutemedia (RPMI) supplemented with $1 \%$ nonessential amino acid, $1 \%$ l-glutamine, $1 \%$ penicillin streptomycin, and $1 \%$ amphotericin B. This solution has a concentration of $0.5 \mathrm{mg} / \mathrm{mL}$ and was stored at $4{ }^{\circ} \mathrm{C}$ until needed.

### 2.4.3.2 Cell lines

Human colon cancer cells (HCT116, ATCC number: CCL-247, human, from the epithelial tissue of the colon), human prostate cancer cells (PC3, ATCC number: CRL-1435, human, from human prostate), and human liver cancer cells (HepG2, ATCC number: HB-8065, human, from the epithelial cells of the liver) were grown in Dulbecco's modified Eagle's medium (DMEM) supplemented with $10 \%$ fetal calf serum, $1 \%$ non-essential amino acid, $1 \%$ l-glutamine, $1 \%$ penicillin streptomycin and $1 \%$ amphotericin B. All cell lines were incubated at $37^{\circ} \mathrm{C}$ in a humidified atmosphere of $95 \%$ air and $5 \% \mathrm{CO}_{2}$, and the culture medium was changed at least twice a week as needed. All chemicals employed were purchased from biological commercial sources except for the amphotericin B and MTT reagent which were obtained from SIGMA and cell lines purchased from ATCC, USA.

### 2.4.3.3 Determination of cell viability

Cell viability was assayed by using the MTT method, which is based on the reduction of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) dye to purple formazan crystals by mitochondrial succinate dehydrogenase enzyme in living cells (47). The cells were seeded into 96well plates at a density of $1 \times 10^{4}$ cells/well and allowed to incubate for 24 h. Cells were then incubated with increasing concentrations of test compounds for another 24 h . At the end of each treatment period, $10 \mu \mathrm{~L}$ of MTT ( $5 \mathrm{mg} / \mathrm{mL}$ in PBS) was added to each well and the microplate was incubated at $37{ }^{\circ} \mathrm{C}$ for 4 h . The medium with MTT was removed and 100 $\mu \mathrm{L}$ of Dimethyl sulfoxide (DMSO) was added to each well to dissolve the insoluble formazan crystals. Plates were incubated for 20 min at $37{ }^{\circ} \mathrm{C}$ and optical densities were measured at 570 nm with a reference wavelength of 630 nm as a background using a spectrophotometer plate reader.

Cell viability was defined as a percentage of absorbance of treated cells to the control.

### 2.4.3.4 In vitro cell growth inhibition assay (MTT assay)

Cells were seeded in 96-well plates at a concentration of $1 \times 10^{4}$ cells/well in $100 \mu \mathrm{~L}$ of complete media and incubated for 24 at $37{ }^{\circ} \mathrm{C}$ in a $5 \% \mathrm{CO}_{2}$ atmosphere to allow for cell adhesion. Stock solutions ( $1 \mathrm{mg} / \mathrm{mL}$ ) of compounds 1 and 2 made in PBS were filter-sterilized, then were further diluted by incomplete media for treatment against cell lines to achieve the following concentration: $1,0.5,0.250,0.125,0.065$, and $0.03125 \mathrm{mg} / \mathrm{mL}$. A
$100 \mu \mathrm{~L}$ solution of each compound was added to a $100 \mu \mathrm{~L}$ solution of fresh medium in wells to give final concentrations of $1-0.03125 \mathrm{mg} / \mathrm{mL}$. All assays were performed in triplicates. A control group containing no drug was run in each assay. After 24 h exposure of cells to compounds $\mathbf{1}$ and $\mathbf{2}$, each well was carefully rinsed with $200 \mu \mathrm{~L}$ of PBS buffer. Cytotoxicity was assessed using MTT solutions ( $5 \mathrm{mg} / \mathrm{mL}$ ) and $100 \mu \mathrm{~L}$ of fresh, complete media which were added to each well. Following a four hour incubation, the medium was removed and the purple formazan precipitated in each well was sterilized in $100 \mu \mathrm{~L}$ DMSO. Absorbance was measured by means of a microplate reader (molecular device) at 570 nm and results are expressed as $\mathrm{IC}_{50}$ values directly calculated from \% viability (directly proportional to metabolic active cell number). Percentage (\%) viability was calculated according to the following equation:
$\%$ viability $=(\mathrm{OD}$ in sample well/OD in control well $) \times 100 \%(\mathrm{OD}=$ optical density)

## Chapter Three

Results and Discussion

### 3.1 Background

Propylenediamine is an excellent primary diaminecomplexing reagent and acts as an N,N-bidentate ligand is capable of coordinating with most of transition metal ions, including $\mathrm{Cu}(\mathrm{II})$ [22,23]. Diamine- $\mathrm{Cu}(\mathrm{II})$ complexes were found to serve as catalysts under mild conditions [24,25]. In addition, copper(II) complexes containing polydiamine ligands have shown high anti-cancer activity which may be due to their ability to inhibit DNA synthesis [27-35]. Recently, we have investigated the spectroscopic and the biological activity of $[\mathrm{Cu}(\operatorname{dipn})(\mathrm{N}-\mathrm{N})] \mathrm{Br}_{2}$ with $[\operatorname{dipn}=$ dipropylenetriamine, $\mathrm{N}-\mathrm{N}=$ ethylenediamine (en) and propylenediamine (pn)] [23].

Although copper complexes have important biological and chemotherapeutic activities, little is known about mono-cationCu(II)diamine complexes in the solid state X-ray single crystal analysis [29-34]. In view of the broad interest in this type of copper(II) complexes, and owing to their biological importance, we describe herein the preparation, characterization, X-ray structure, and surface studies of new water soluble mono-cation $\left[\mathrm{CuX}(\mathrm{N}-\mathrm{N})_{2}\right]^{+} \mathrm{X}^{-}$complexes $\left(\mathrm{X}^{-}=\mathrm{Cl}^{-}\right.$and $\left.\mathrm{Br}^{-}\right)$. In addition, the antitumor activity of the desired complexes against different cancer cell lines has been investigated.

### 3.2 Synthesis of aqua bromo-bis-(1,3-diamine)copper(II) bromide complexes 1-4

As shown in Scheme3.1, copper(II) complexes, with the general formula $\left[\mathrm{CuX}(\mathrm{N}-\mathrm{N})_{2}\right] \mathrm{X}$, were prepared by reaction of1,2-ethylenediamine/ 1,3propane--diamine with a copper(II) halide in an ethanol-water mixture and in a 2:1 ligand -to-metal ratio. The complexes have been prepared, in good yields, as water-soluble chloride and bromide salts, respectively. Furthermore, these complexes were blue in color and the reactions that led to their formation were highly exothermic. These newly synthesized complexes were characterized by elemental and spectral analysis.

$\mathrm{X}=\mathrm{Cl}$ (complex 1), Br (complex 2)
Scheme 3.1: Synthesis of complexes $\mathbf{1 , 2 , 3}$ and 4.

### 3.3 Crystal structure determination and Hirshfeld surfaces analysis

Complex 2 contains a mononuclear copper(II) complex mono-cation, bromide ion $(\mathrm{Br} 13)$, and a dehydrated water molecule $(\mathrm{O} 14)$ as depicted in Figure 3.2.

Figure 3.2: ORTEP diagram of complex 2 with thermal ellipsoids drawn at $50 \%$ probability.

For this complex, the central $\mathrm{Cu}(\mathrm{II})$ ion coordinates with four nitrogen atoms (N2, N6, N8, and N12) and one bromide ion (Br7) and attains a square pyramidal (CuN4Br) coordination geometry. An intramolecular hydrogen bond C11---H11B...Br7 with a distance of 3.584 (4) Å (angle $127^{0}$ ) is observed. Furthermore, the intermolecular hydrogen bonds $\mathrm{N} 2---$ $\mathrm{H} 2 \mathrm{~A} \ldots \mathrm{Br} 7\left(\right.$ distance $=3.476(3) \AA$, angle $=155^{\circ}$ and symmetry $=1-x, 1-y$, -
z), N2---H2B...Br13 (distance $=3.533$ (3) Å, angle $=161^{\circ}$ and symmetry $=$ $1-x, 1-y,-z)$, N6---H6B...Br7 (distance $=3.399(4) \AA$ and angle $\left.=130{ }^{\circ}\right)$, N8---H8B...Br7 (distance $=3.550(4) \AA$, angle $=154^{\circ}$ and symmetry $=$ $x, 3 / 2-y,-1 / 2+z), \mathrm{N} 12---\mathrm{H} 12 \mathrm{~A} \ldots \mathrm{Br} 13\left(\right.$ distance $=3.569(3) \AA$, angle $=127^{\circ}$ and symmetry $=x, 3 / 2-y, 1 / 2-z)$ and N6---H6A...O14 (distance $=2.990$ (6) $\AA$, angle $=152^{\circ}$ and symmetry $\left.=1-x, 1-y, 1-z\right)$ connect the molecules in 3D architecture (Figure 3.3 along a, along b, along c) in the crystal packing.

Figure 3.3: Molecules packing viewed down along the $a-, b$-, and $c$-axis.

Figure 3.4: ORTEP diagram of complex 4 with thermal ellipsoids drawn at $50 \%$ probability.

Figure 3.5: Above: Molecules packing viewed down along the $a$-, $b$-, and $c$-axis,down:
Molecules interactions viewed

Displayed in Figure $\mathbf{3 . 6}$ is the Hirshfeld surface of compound 2. Hydrogen bonds and other sufficient intercontactswere indicated by red spots over whole molecule surface $[40,41]$. The dark-red one spots on the $\mathrm{d}_{\text {norm }}$ appear as a result of the short interatomic contacts, whereas long interactions raise as light-red spots.

Figure 3.6:Hirshfeld surface $d_{\text {norm }}$ map visualizing the complex 2 intercontacts. Color scale in between -0.18 au (blue) to 1.4 au (red).

The 2D Finger print plots over the Hirshfeld surfaces show the presence of intercontacts H...H (52.8 \%), H...Br (32.7 \%), H...O (12.4 \%) and Br...O (2.1 \%) (Figure 3.7). The major contribution, however, comes from H...H whereas the least contribution arises from Br ... O .

Figure 3.7 Fingerprint of complex 2, (a) H...H, (b) H...Br, (c) H...O, (d) Br...O, and (e) Full.

Figure 3.8: Hirshfeld surface $d_{\text {norm }}$ map visualizing the complex 2 intercontacts. Color scale in between -0.28 au (blue) to 1.21 au (red).

Figure 3.9: Fingerprint of complex 4.

### 3.4 Elemental analyses and mass spectrum

The mass spectrum and elemental analysis of the desired complexes are consistent with their proposed molecular formula. As an example complex 2. Calc. for $\mathrm{C}_{6} \mathrm{H}_{20} \mathrm{Br}_{2} \mathrm{CuN}_{4}$ : C, 19.39; H, 5.42; N, 15.08. Found: C, 19.15; H, 5.21 ; N, $14.92 \%$. TOF-MS of 2 is in agreement with its structure showing $\left[\mathrm{M}^{+}\right]=292.2 \mathrm{~m} / \mathrm{z}$, (290.4 theoretical) as in Figure 3.10.

Figure 3.10: TOF-MS spectrum of complex 2.

### 3.5 FT-IR spectral analysis

The FT-IR of complexes showed similar behavior, IR of $\mathbf{1}$ and $\mathbf{2}$ are given in Figure 3.11 IR spectra revealed strong absorption bands in 3300-3200 and $1650-1520 \mathrm{~cm}^{-1}$ assigned to $v_{\mathrm{s}} / v_{\mathrm{as}}(\mathrm{N}-\mathrm{H})$ and $v_{\mathrm{b}}(\mathrm{N}-\mathrm{H})$, respectively; such bands are slightly shifted to lower wavenumbers, and are sharper than those of the free primary diamine, indicating the coordination of the $-\mathrm{NH}_{2}$ groups with $\mathrm{Cu}(\mathrm{II})$ center. The strong bands in the range $2950-2850 \mathrm{~cm}^{-1}$ are attributed to the $\mathrm{C}-\mathrm{H}$ stretching vibrations of $\mathrm{sp}^{3} \mathrm{CH}_{2}$ groups in the diamine ligand [43]. In addition, the band at $610-500 \mathrm{~cm}^{-1}$ is assigned to $v_{(\mathrm{Cu}-\mathrm{N})}$ vibrations [44,45].

Figure 3.11 The FT-IR spectra of complex 1 a) and complex 2 b).

### 3.6 UV-Vis. spectral analysis

Complexes 1 and 2 UV-Vis. spectra were recorded in distilled water at room temperature. The complexes exhibited absorption bands at $\lambda_{\max }=250$ nm (complex 1) and 255 nm (complex 2), as seen in Figure 3.12, corresponding to $\pi-\pi^{*}$ transition. Additionally, the absorption bands at $\lambda_{\max }$ $=580($ complex 1) and 568 nm (complex 2), in the blue color region are due to the d-d electronic transition [29-33].

Figure 3.12: UV-Visible spectra of $1 \times 10^{-4} \mathrm{M}$ : a) 1 , and b) $2 \mathrm{in} \mathrm{H}_{2} \mathrm{O}$ and at room temperature.

### 3.7 Solvatochromism

Solubility of the newly prepared complexes in polar solvents limits the number of solvents which can be used to evaluate the solvatochromism phenomena in these compounds. For this reason, we have used $\mathrm{H}_{2} \mathrm{O}, \mathrm{EtOH}$, DMF, and DMSO in this investigation. Vis. Absorption spectra of complex 2 in selected solvents are seen in Figure 3.13. The visible spectra of this complex in different solvents reveal absorption bands in the region 420-800 nm . Solvatochromic probes in such solvents are ascribed to strong expected Jahn-Teller effect of copper(II) ion ( $\mathrm{d}^{9}$ ).

Figure 3.13 Absorption spectra of 2in selected solvents.

Bathochromic color changes shift was observed and is attributed to the direct coordination of the polar solvent to the vacant sites of the $\mathrm{Cu}($ II $)$ center with different strengths, which is in agreement with the mechanism of solvatochromism behavior of such complexes [46-48].Accordingly, the visible bands chemical shift increases linearly with increasing the Gutmann's donor values (DN) of the solvent. The linear trend of $\lambda_{\max }$ of complex 2 against DN is presented in Figure 3.14.

Figure 3.14 Dependence of $\lambda_{\max }$ of complex 2 on the solvent's Gutmann donor number values.

### 3.8 Thermogravimetric analyses

In the current investigation, we have performed thermal analyses (TG/DTG) to collect information upon stability of complex 4. To perform these measurements, the temperature was increased from 0 to $900{ }^{\circ} \mathrm{C}$ at a heating rate of $10{ }^{\circ} \mathrm{C} \mathrm{min}^{-1}$. Displayed in Figure $\mathbf{3 . 1 5}$ are the resulting TGA curves for complex 4.

Figure 3.15 TG/DTG thermal curve of complex 4 (TG is the thick solid line, other line represents DTG).

Results from thermogravimetric analysis of the complex revealed the occurrence of three consecutive mass losses; dehydration, organic ligand pyrolysis, inorganic ligand de-structure to metal oxide residue formation.

The first step which involved loss of uncoordinated water molecule was at $\sim 100^{\circ} \mathrm{C}$. In the second decomposition stage, the diamine ligand was lost in the temperature range of $200-280{ }^{\circ} \mathrm{C}$ to form $\mathrm{CuBr}_{2}$. At higher temperatures, the complex undergoes further decomposition that eventually leads to production of copper(II) oxide $(\mathrm{CuO})$; this stage takes place in the temperature range of $580-620^{\circ} \mathrm{C}$.

### 3.9 CT-DNA binding

## CT-DNA binding affinity of complexes (absorption titration)

UV visible absorption titration spectroscopy is one versatile methods to estimate DNA-binding affinity [48]. The affinity of the complexes toward CT-DNA was followed by UV-visible titrations in Tris- HCl buffer solution. Typically, changes are expected inUV spectra of the desired compound bydrug-DNA binding [51].Figure 3.16 showing the UV-Visible spectra titration of complex $\mathbf{1}$ upon CT-DNA addition.

Fig. 3.16: $5.0 \times 10^{-5} \mathrm{M}$ of complex 1 UV-Vis. spectra interacted with a) 0, b) $1.0 \times 10^{-6}, \mathrm{c}$ ) $\left.5.0 \times 10^{-6}, \mathrm{~d}\right) 1.0 \times 10^{5}$ and e) $1.0 \times 10^{-4} \mathrm{M}(\mathrm{a} \rightarrow \mathrm{e})[\mathrm{DNA}]$ at RT. Plot of $[\mathrm{DNA}] /\left(\varepsilon_{\mathrm{a}}-\varepsilon_{\mathrm{f}}\right)$ $v s$.[DNA] at $\lambda_{\max }=250 \mathrm{~nm}$ to determine the intrinsic binding constant $\mathrm{K}_{\mathrm{b}}$.
$5 \times 10^{-5} \mathrm{M}$ of the complexes were treated with several DNA concentrations ranging from 0 to $1 \times 10^{-4} \mathrm{M}$ in order to monitor the decrease in absorption at $\lambda_{\max }=250 \mathrm{~nm}$, as seen in Figure 3.17. To evaluate the binding ability of investigated complexes, $\mathrm{K}_{\mathrm{b}}$ (intrinsic binding constant) for both complexes was evaluated by observing the changes in Abs. vis. CT-DNA concentrations by using the following equation [49-53]:
$[D N A] /\left(\varepsilon_{a}-\varepsilon_{f}\right)=[D N A] /\left(\varepsilon_{b}-\varepsilon_{f}\right)+1 / K_{b}\left(\varepsilon_{b}-\varepsilon_{f}\right)$
[DNA] is the concentrations of DNA in base pairs, $\varepsilon_{\mathrm{f}}, \varepsilon_{\mathrm{a}}$, and $\varepsilon_{\mathrm{b}}$ are the free-, apparent-, and metal-bound-complex extinction coefficients, respectively. $\mathrm{K}_{\mathrm{b}}$ is the equilibrium binding constant (in $\mathrm{M}^{-1}$ ) of complex binding to DNA. When plotting [DNA] / $\left(\varepsilon_{\mathrm{a}}-\varepsilon_{\mathrm{f}}\right) v s$ [DNA], $\mathrm{K}_{\mathrm{b}}$ was obtained from the ratio of the slope to intercept. $\mathrm{K}_{\mathrm{b}}$ for complex $\mathbf{1}=1.30 \times 10^{4} \mathrm{M}^{-1}$ (as seen in Figure 3.16) and $1.15 \times 10^{4} \mathrm{M}^{-1}$ for complex 2. These results are similar to those obtained by other researchers for $\mathrm{Cu}(\mathrm{II})$ complexes[4953].

### 3.10 Proliferation assay

The MTT cell assay has been widely accepted as a reliable way to measure the cell proliferation rate, and conversely when metabolic events lead to apoptosis or necrosis [47]. Data obtained from the present study by the MTT assay indicated that both complexes have inhibitory effects on the growth of HCT116 colon, HepG2 liver, and PC-3 prostate cancer cells in a dose-dependent manner. In addition, the cytotoxicity of these complexes decreases in a time-dependent fashion. Furthermore, the $\mathrm{IC}_{50}$ values for both complexes were found to be $31.25 \mu \mathrm{~g} / \mathrm{mL}$ at 24 h of treatment. The importance of such work lies in the possibility that the next generation of metal complexes might be more efficacious as anticancer agents. However, more detailed studies are required to establish the safety and efficacy of these compounds and to have a structure-activity profile for these complexes. Similarly, it is equally important to have an idea about their
stability under biological conditions is required. These detailed investigations could be helpful in designing more potent anticancer agents for therapeutic uses. Furthermore, we performed survival studies where cells were incubated, separately with complexes $\mathbf{1}$ and $\mathbf{2}$, and then washed to remove the metal complexes. The cell survival was determined at complex concentrations ranging from 1 to $0.03215 \mathrm{mg} / \mathrm{mL}$ ). At these concentrations, complex 1 was able to kill $78,82,83,84,86$, and $87 \%$ of the HCT116 cells, respectively, as depicted in Figure 3.17.

Figure 3.17.Inhibitory effects of complex 1 on the proliferation of HepG2 liver cancer cells, PC3 and HCT 116.

On the other hand, complex 2 at the same concentrations was able to kill $78,81,82,82,83$, and $84 \%$ of the HCT116 cells, respectively, as shown in Figure 3.18.

Figure 3.18: Inhibitory effects of complex $\mathbf{2}$ on the proliferation of HepG2 liver cancer cells, PC3, HCT 11.

## Chapter Four

## Conclusions

Four new mono-cation propane-1,3-diamines/Cu(II) complexes were prepared and characterized in goodyeilds. The structures of the complexes were determined by several spectral and thermal measurements. Complex 2 demonstrated positive solvatochromism due to coordination of polar solvent molecules with different DNA to the axial site of the $\mathrm{Cu}(\mathrm{II})$ center. The single crystal X-ray diffraction data for complex 2 showed that copper ion is in a distorted square pyramid environment. The CT-DNA binding and antitumor activities of the complexes were evaluated; results revealed high CT-DNA binding and antitumor activity against several types of cancer cells.

## Supplementary material

Crystallographic data for complex 2 have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication number CCDC 1422015. Copies of this information may be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK; fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk).

## الملخص

إن بحثنا تركز على تحضير مركبات جديدة التي من المتوقع ان تدعم كيمياء التتسيق بقوة وامتياز .وأنتجت أربعة مركبات جديدة من مركبات أحادي الايون المائي بوجود العنصر الأساسي النحاس الثنائي Cu(II) مع Cu (1,3-propylenediamine و 1,2-ethylenediamine مع كلور أو بروم بروابط في عائد مقبول.وقد تم وصف المركبات طيفيا (الأشعة تحت الحمراء، الأشعة فوق البنفجية مرئية، وتوف-مس) وكذلك الحرارية (TG/DTA) والتحليل العنصري. تم إثبات التركيب ثلاثي الأبعاد للمركبات 2،4 من خلال دراسات حيود الأشعة السينية، والتي تبين أن Cu(II) يتم تتسيقها بواسطة أربع ذرات نيتروجين و أيون بروم أو أيون كلور . N - في التركيب البلوري ترتبط الجزيئات من خلال تفاعلات ثنائي القطب بين الجزيئات من النوع Br ... -- H هيدروجينية داخل الجزيئات من نوع Br ... C --- H ؛ هذه التفاعلات تؤدي إلى تقوية الترابط داخل الكريستال ثلاثية الأبعاد.تم استخدام طريقة حسابية هيرشفيلد لمعرفة الطريقة المتداخلة في التركيب البلوري، وأظهرت البيانات أن الروابط الداخلية من نوع H...H بنسبة (52.8\%) و
 تم رصدها كميا.

وقد تم تقييم النشاط المضاد للورم من المركبات المنتجة، وكثفت النتائج عن نشاط عال مضاد للورم ضد عدة أنواع من الخلايا السرطانية.
